

Grid-Based Renewable Electricity and Hydrogen Integration

Carolyn Elam

Senior Project Leader – Hydrogen Production

Electric & Hydrogen Technologies & Systems Center

National Renewable Energy Laboratory

Goals for Electrolysis in Hydrogen Fuel Supply

- Goal is to supply hydrogen fuel for 20% of the light-duty vehicle fleet
 - 12 million short tons of hydrogen annually
 - 450 TWh per year
- Must be competitive
 - With gasoline, assuming FCV will have twice the efficiency of an ICE
 - With other hydrogen production methods
- Net zero impact or reduction in GHG emissions
 - Compared to Gasoline ICE - 31% reduction in carbon emissions from the current electricity mix
 - Compared to Natural Gas-Derived Hydrogen - 65% reduction in carbon emissions from the current electricity mix

Goals for Electrolysis (cont.)

- Need to cut the cost of hydrogen production via electrolysis in half
 - Lower feedstock cost (electricity)
 - Lower capital cost
- No net increase in carbon emissions
 - Improve efficiency of current generation mix
 - Increase market share for low- and no-carbon electricity sources
- But is this possible?

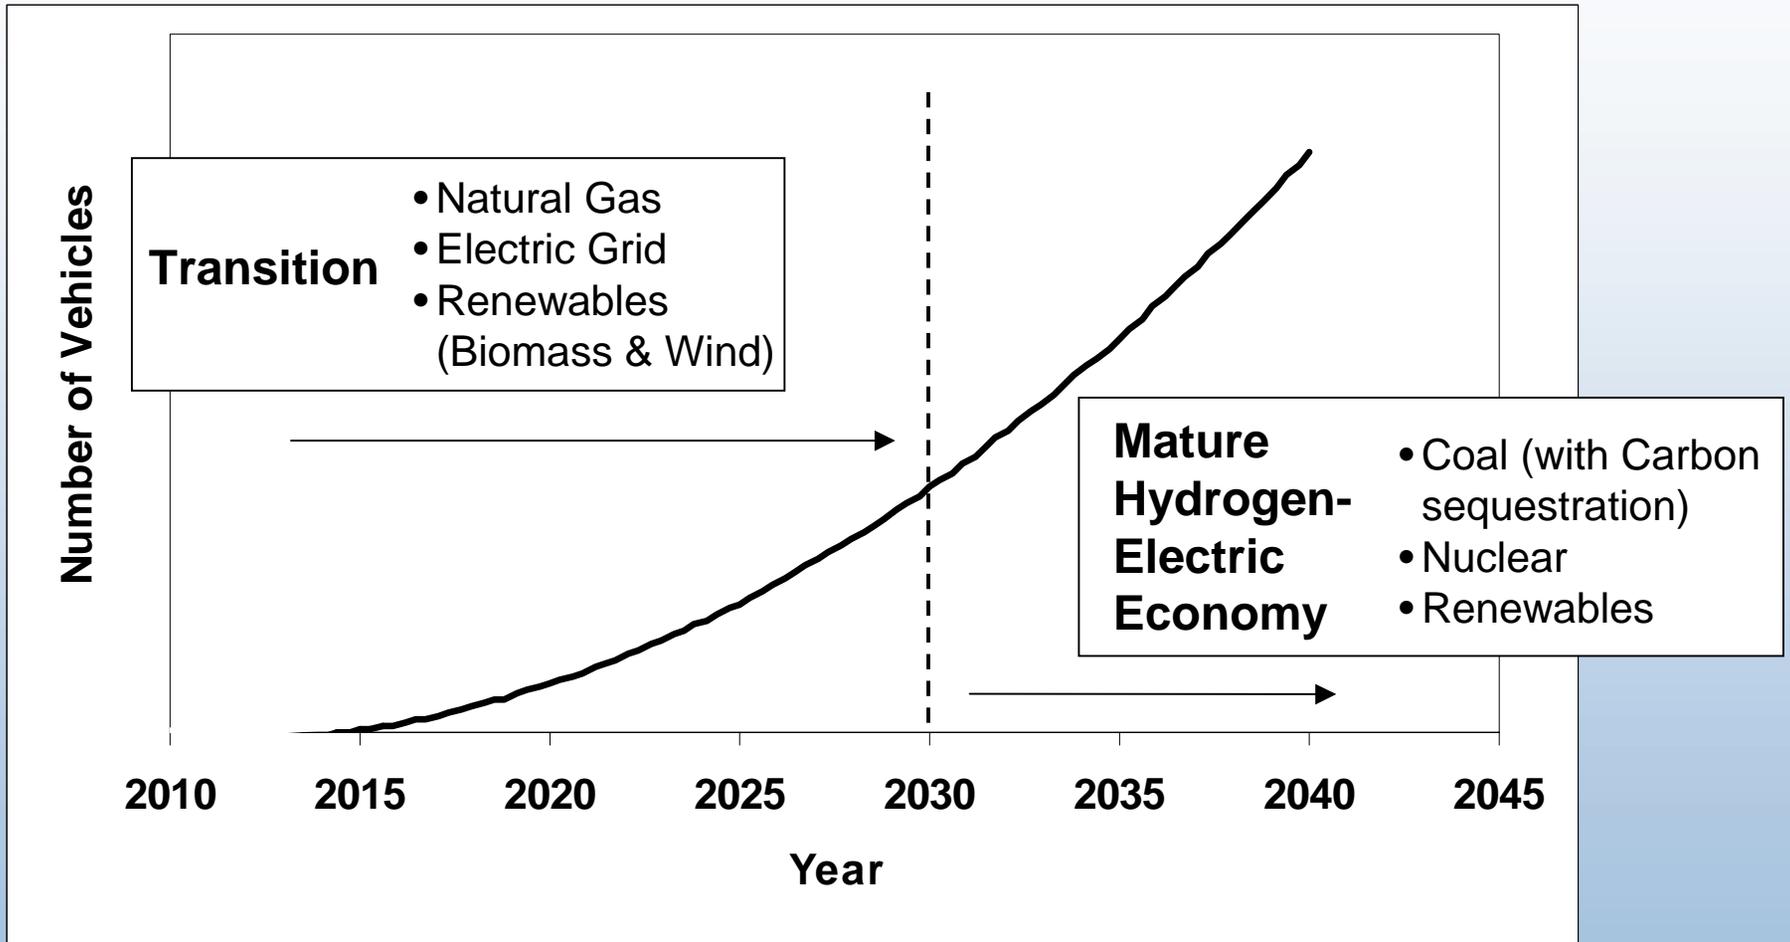

Figuring out the potential....

To answer this question we need to understand:

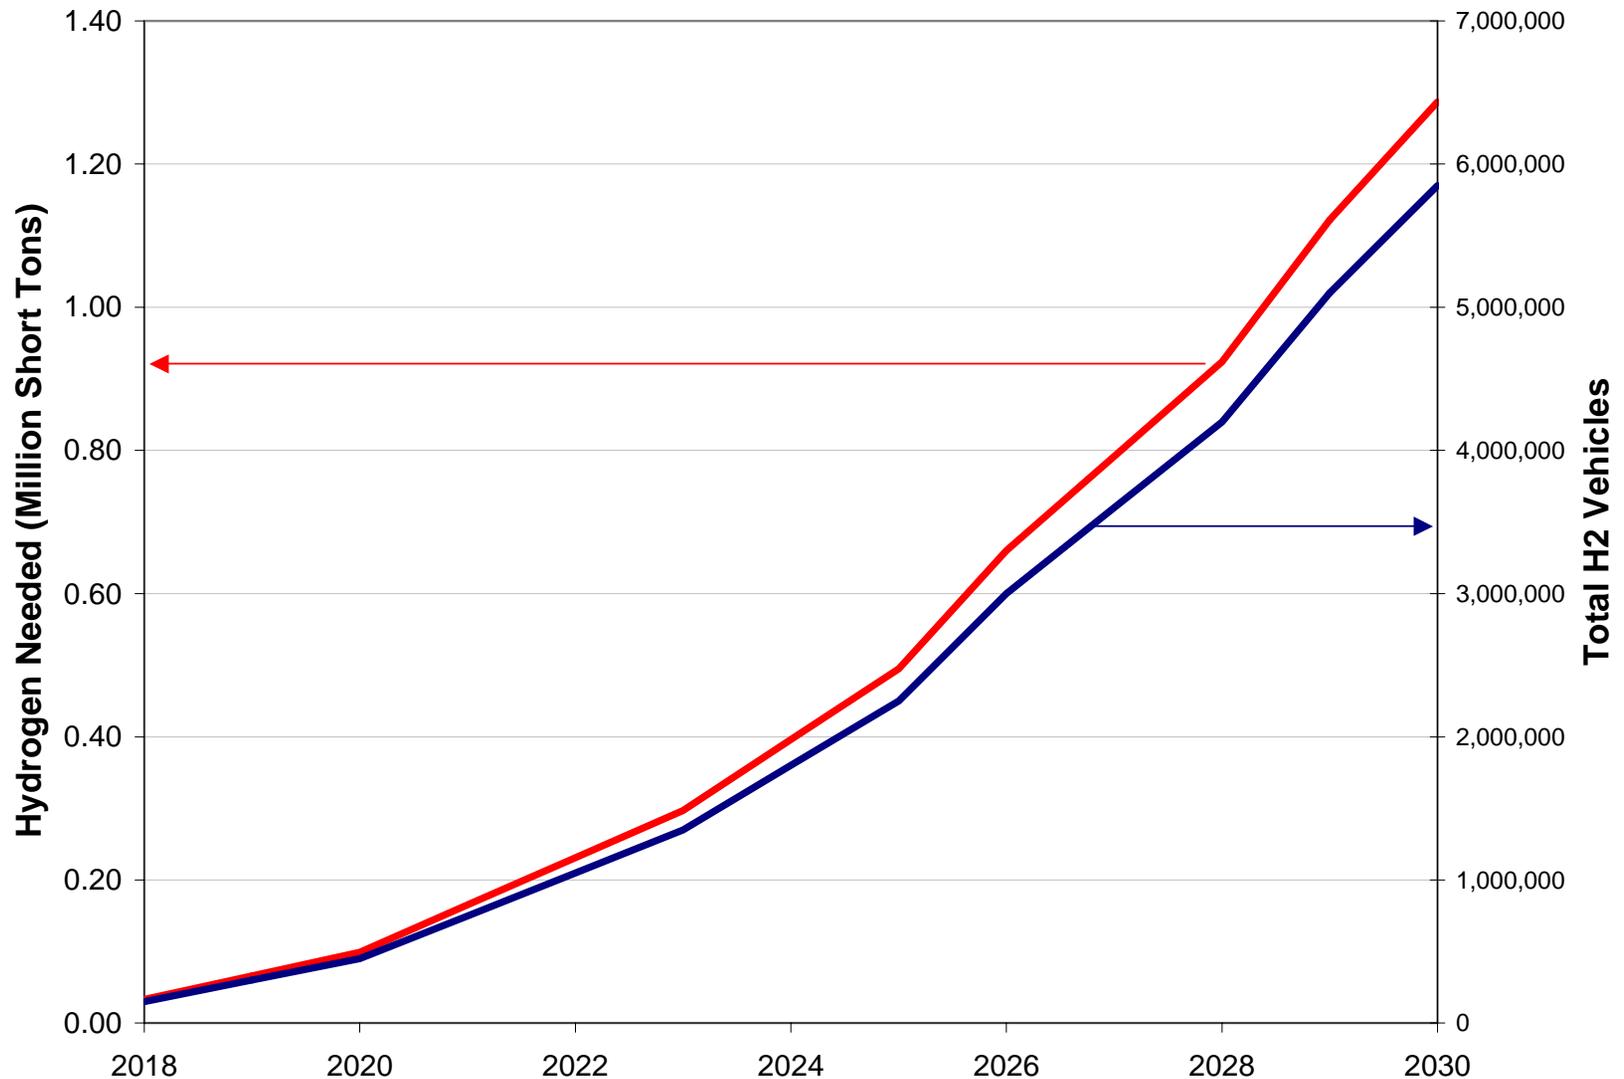

- Cost impacts, including requirements for capital, storage, and feedstock (electricity)
- How much hydrogen will be required, where, and when
 - Amount that could be produced by electrolysis
 - Competition
- Potential of non-carbon electricity sources
 - Resource availability
 - Cost
 - Impact on transmission and distribution

This represents a multi-level analysis issue.

Moving Toward a Hydrogen-Electric Future

How much hydrogen?

How much Hydrogen?

- Transition Period
 - Sufficient stations to enable interstate travel
 - Accessible in urban areas
- Major Market Share
 - ~120,000 hydrogen fuel stations
 - Convenient in urban areas
 - Accessible in rural areas

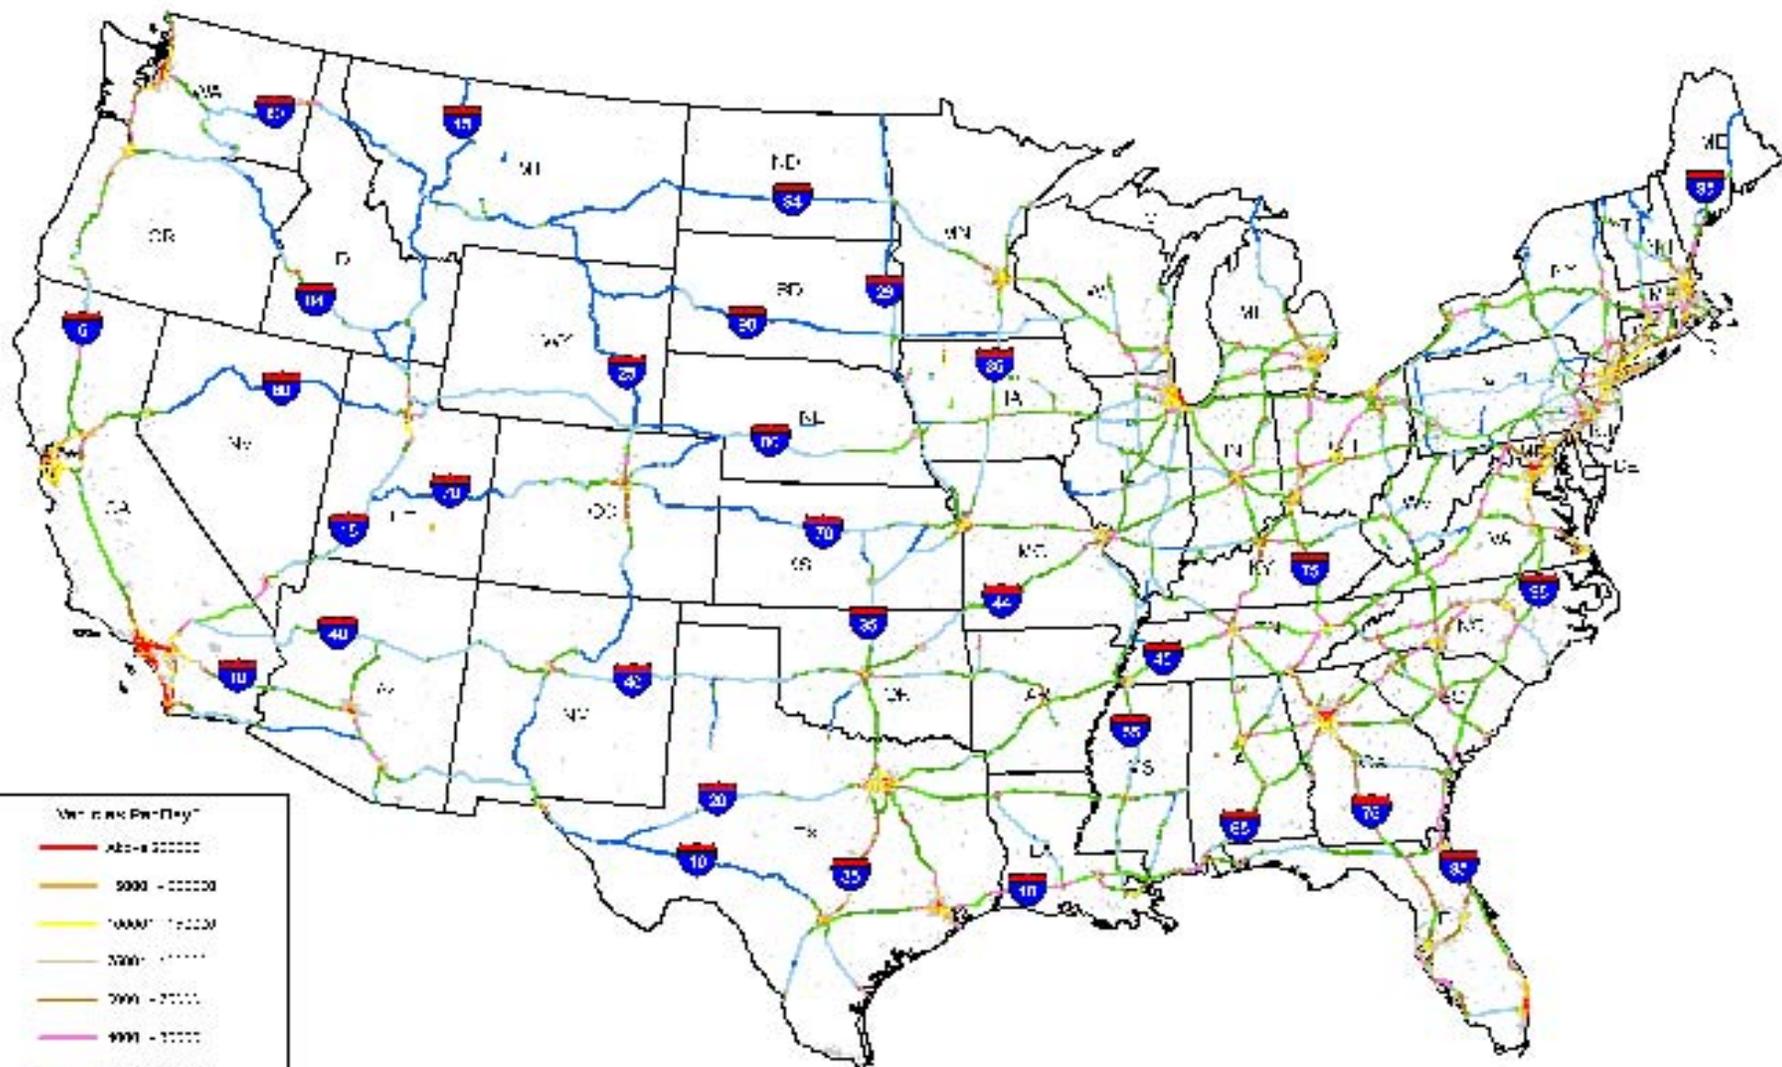

Where do we build hydrogen stations?

For the transition phase:

- Use existing hydrogen fueling stations
- Build near existing hydrogen production facilities
- Co-locate at existing alternative fuels stations

2002 Annual Average Daily Traffic

Volume Per Day

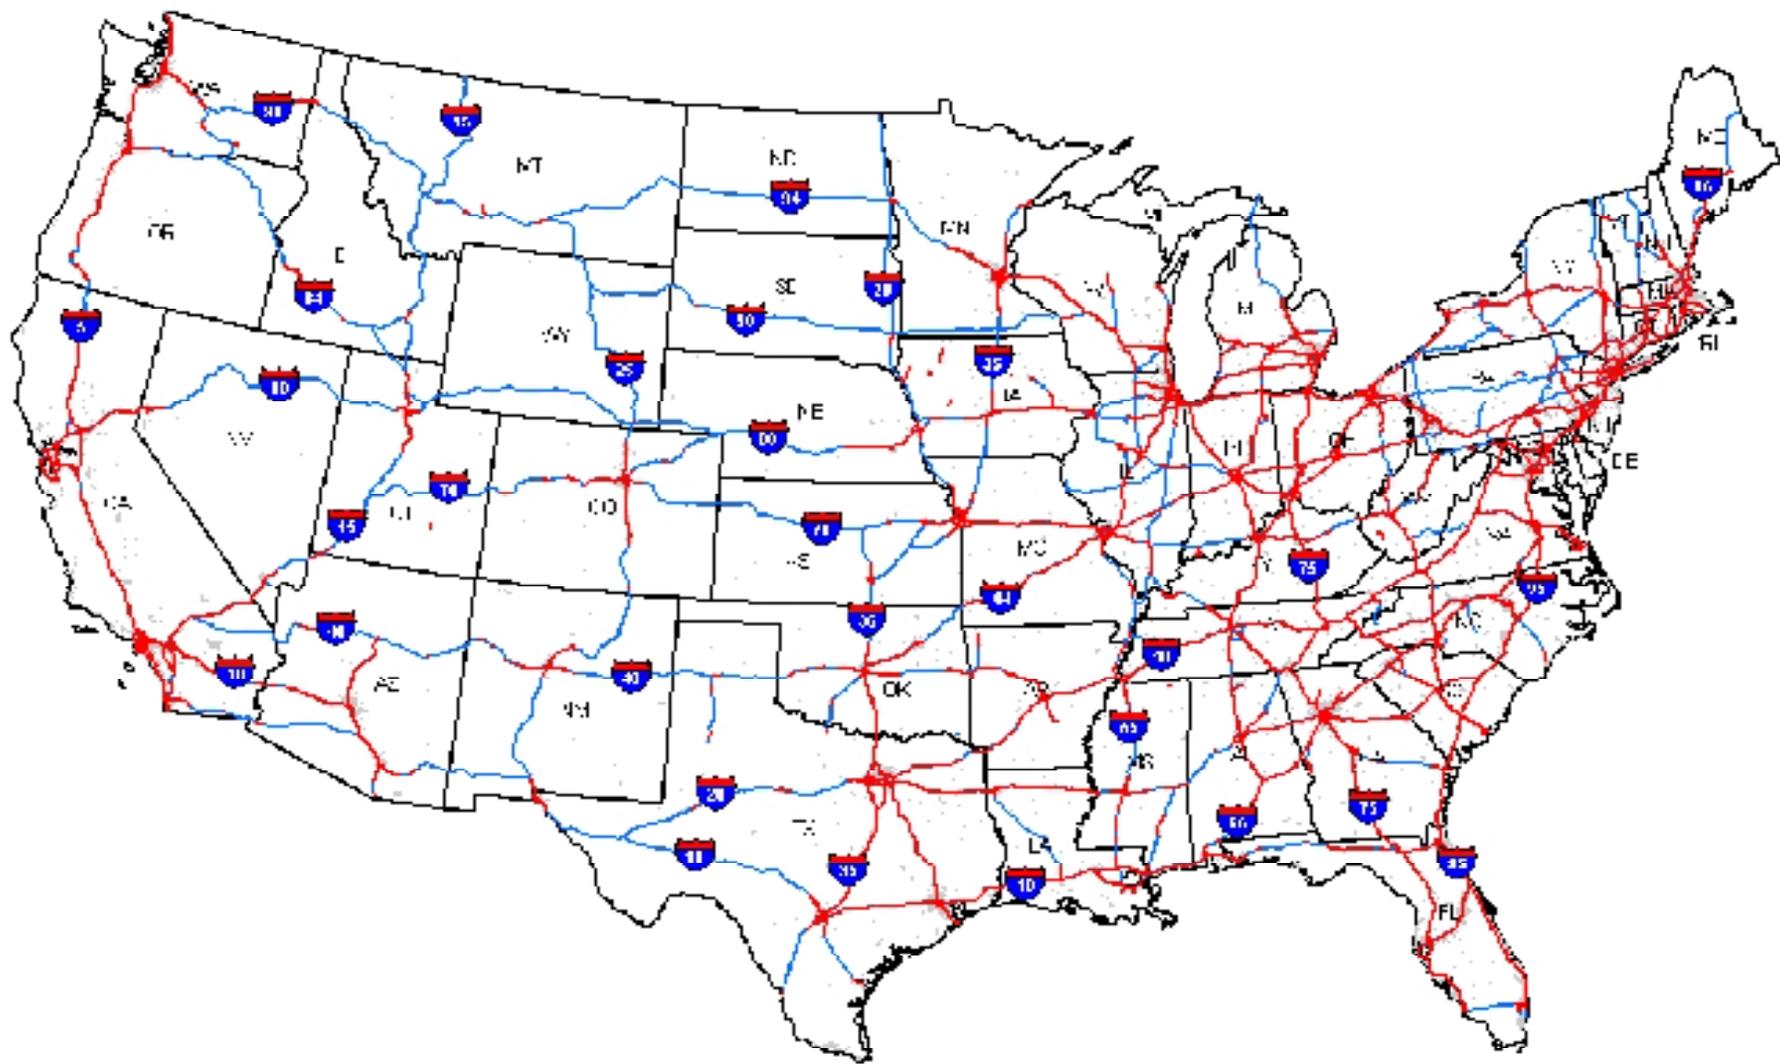

- 100,000 - 200,000
- 50,000 - 100,000
- 10,000 - 50,000
- 5,000 - 10,000
- 2,000 - 5,000
- 1,000 - 2,000
- 500 - 1,000
- 100 - 500
- Less than 100

Market Analysis Using WinDS-H2

- A multi-regional, multi-time-period model of capacity expansion in the electric sector and hydrogen production in the U.S
- Designed to estimate market potential of wind energy and hydrogen from wind in the U.S. for the next 20 – 50 years under different technology development and policy scenarios

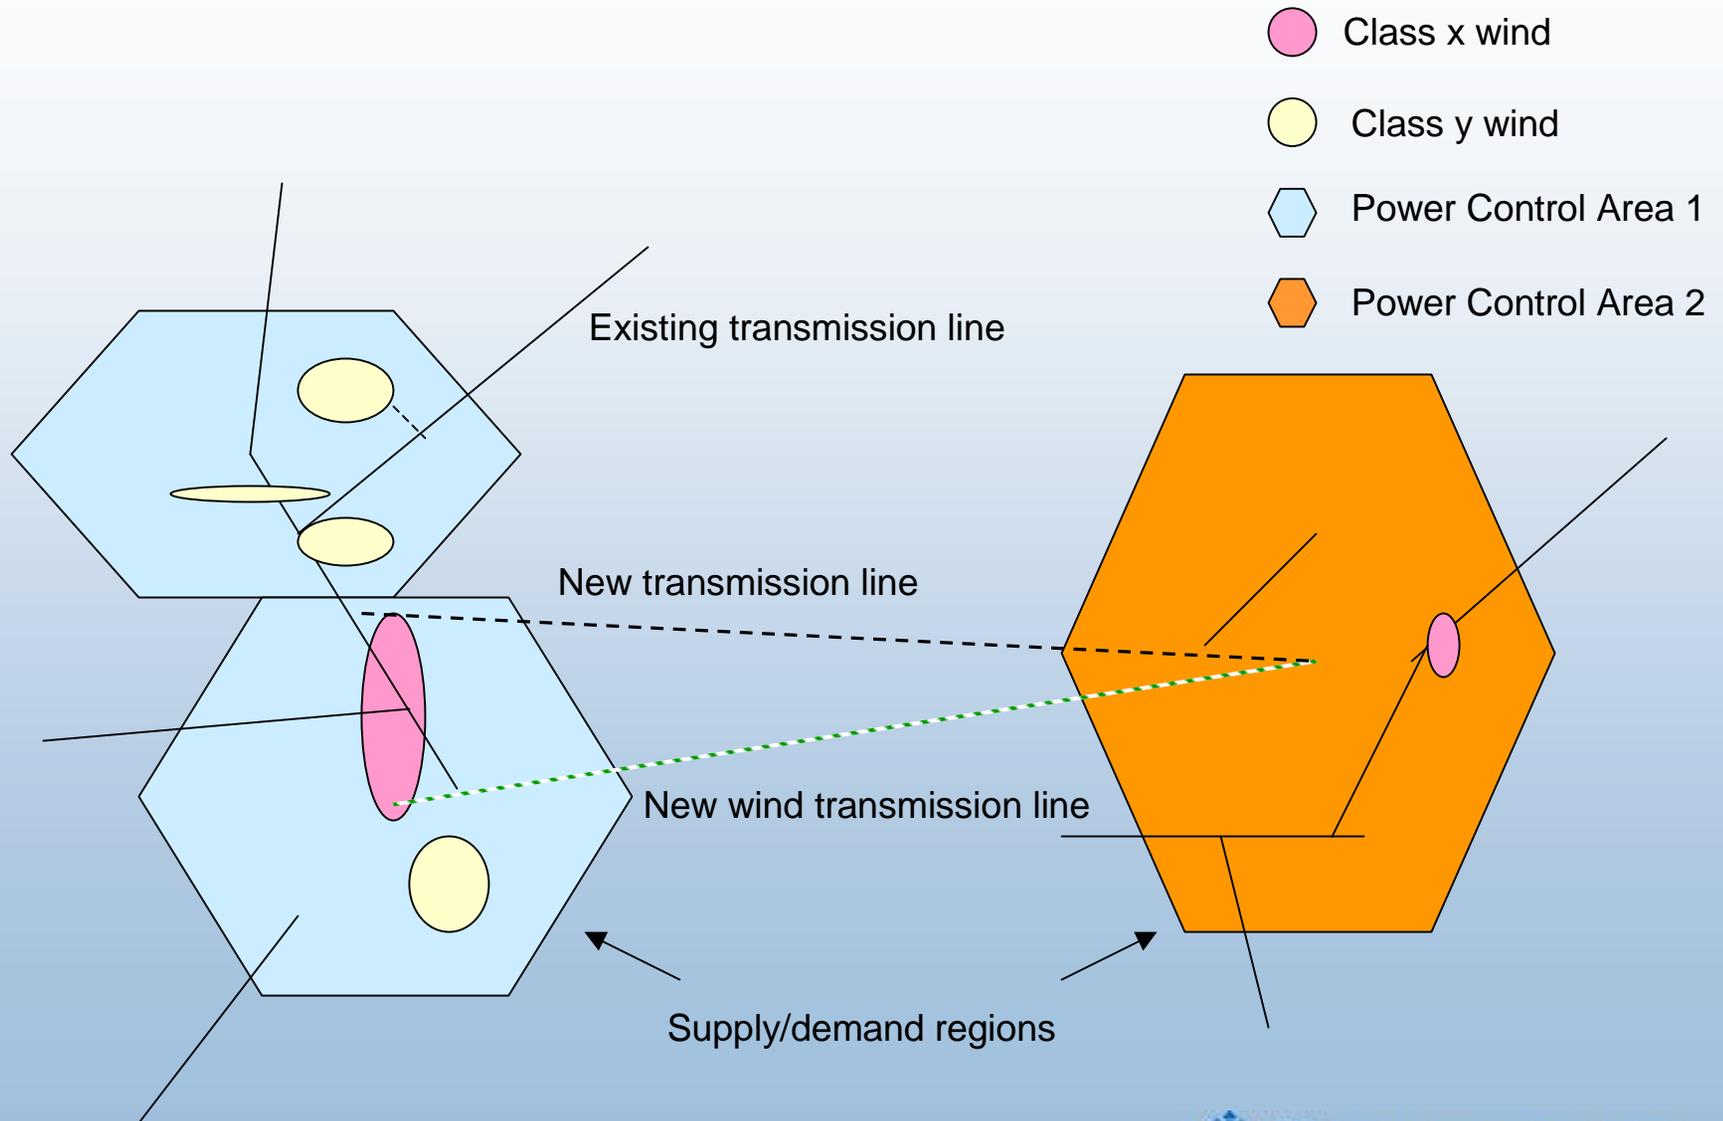

Market Analysis Using WinDS

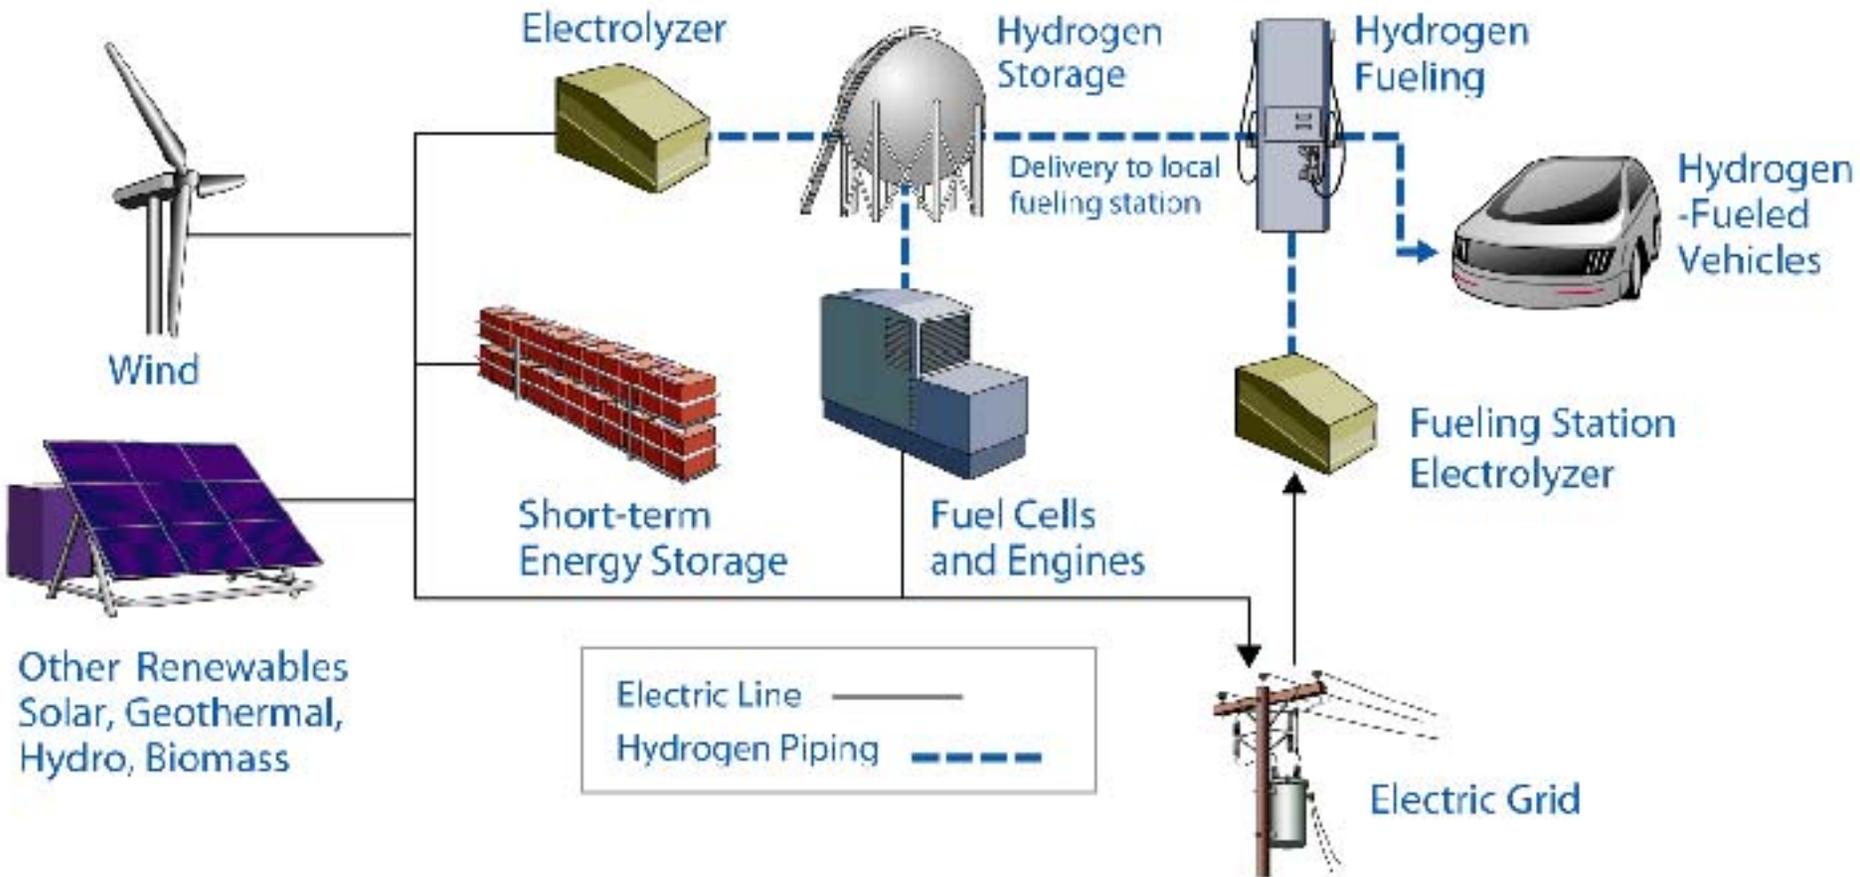

Wind Resources

Constraints on Wind Transmission

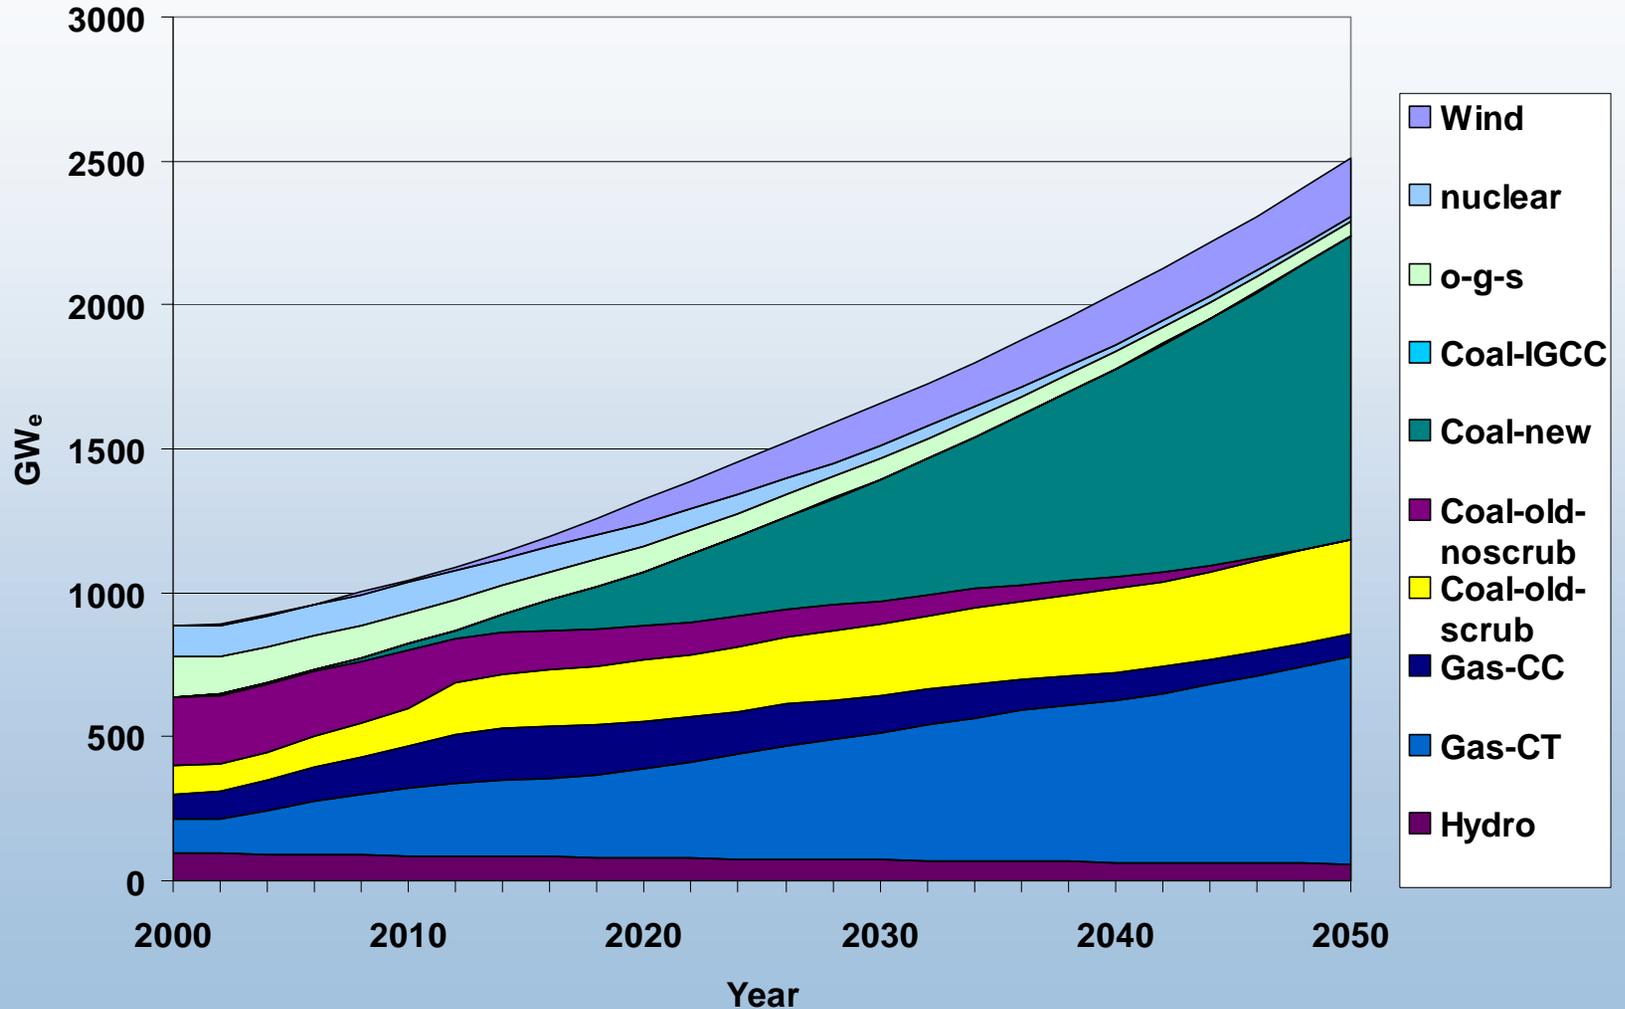

Electrolysis Options

Cost/Performance for Class 6 Wind Resources

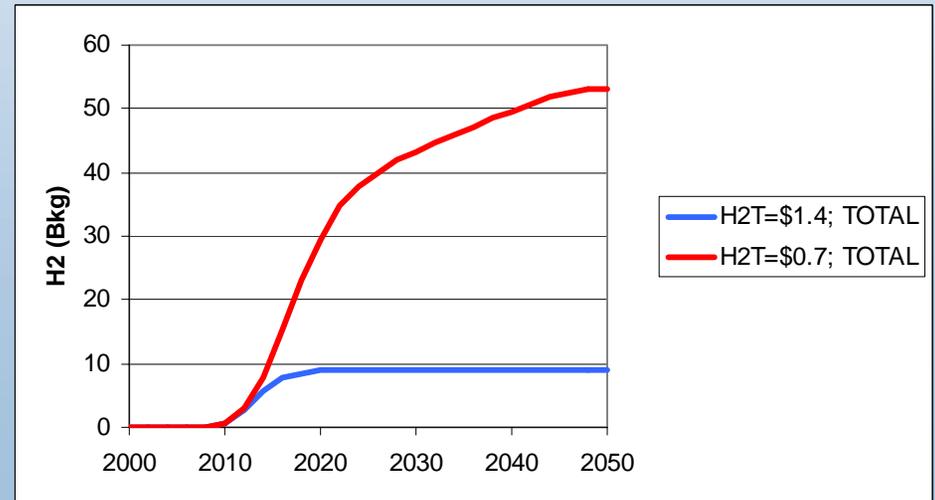

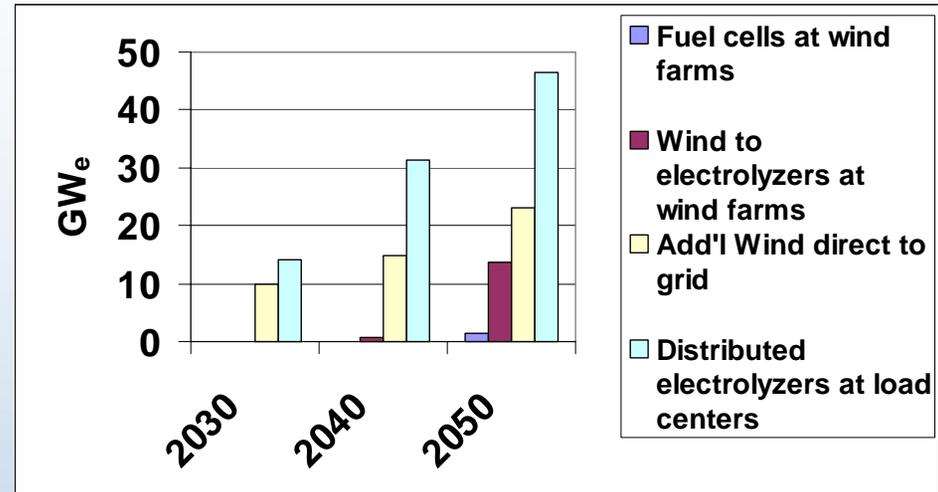

Year	Capital Cost (\$/kW)	Capacity Factor
2000	942	0.4
2010	754	0.5
2020	706	0.54

Base Case Results

Cases Considered (so far)

- Low-cost high-efficiency electrolyzers
 - Electrolyzers show up at both the wind farm and the load center
 - More wind to grid
- Sensitivity to hydrogen delivery cost
 - Hydrogen delivery distance/cost will have significant impact
- Increased wind penetration depends heavily on hydrogen conversion device (i.e. fuel cell) cost and efficiency

Integration with Renewables: Research Opportunities

- Co-producing electricity and hydrogen can address issues that currently face intermittent and season renewable technologies
- Wind/electrolysis could be the first economical renewable system
- R&D: hybrid system optimization, power electronics, system design

Component Development

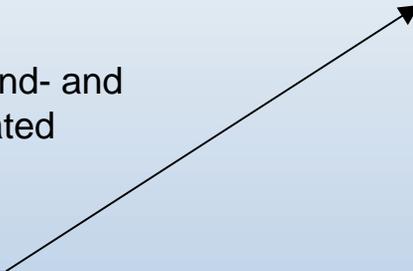

Grid Electricity

Dedicated Test Bay for Electrolytic Hydrogen Production

On-Site Wind- and PV-Generated Electricity

Shared Power Electronics Package

Component Development

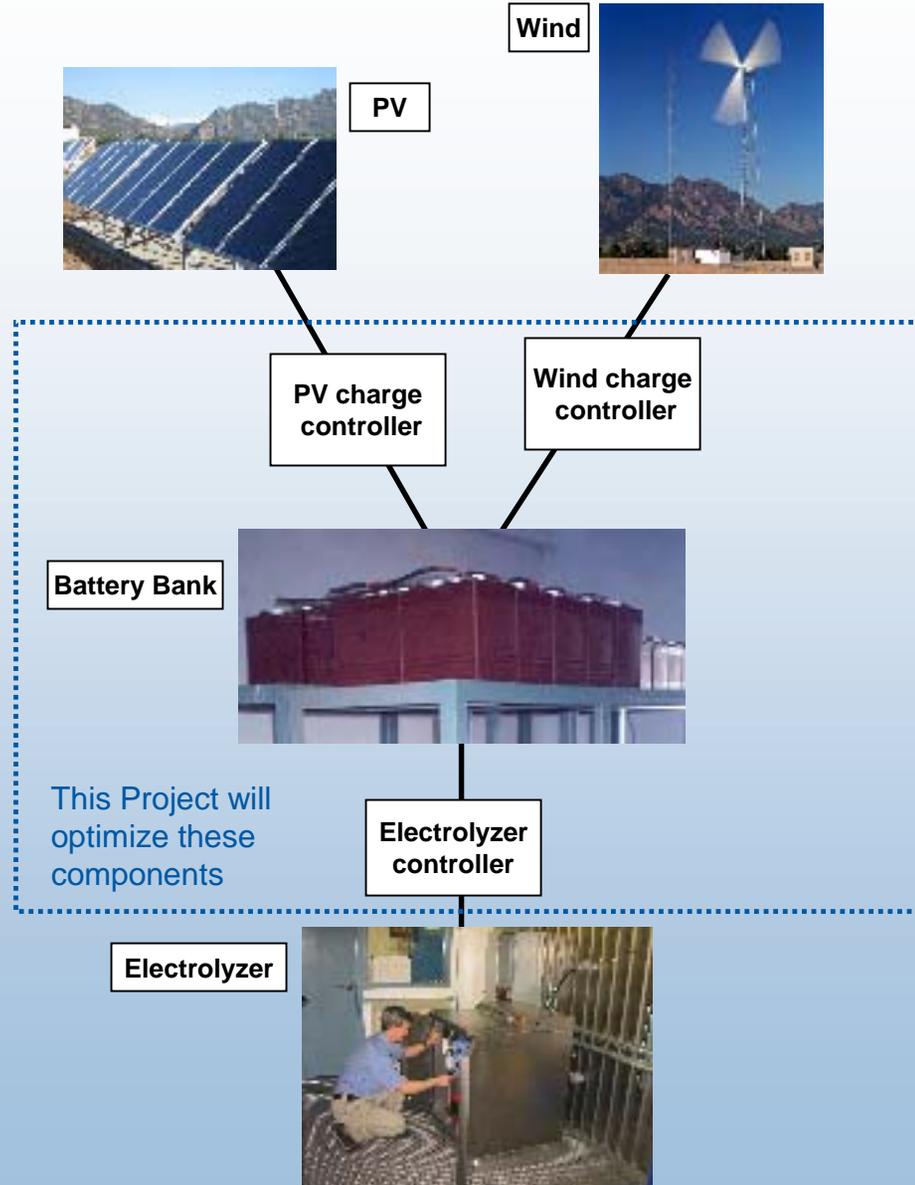

Past research on integrating electrolyzers with renewables has focused on integrating commercially available electrolyzers and renewables, both complete with their own dedicated power electronics and controller.

Designing a single power electronics package and controller will:

- Eliminate this redundancy
- Allow matching of renewable power output to electrolyzer power requirements leading to gains in system efficiency.

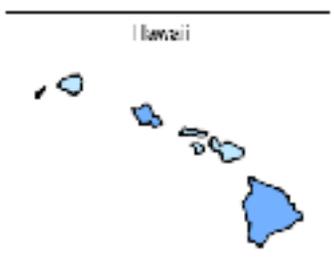

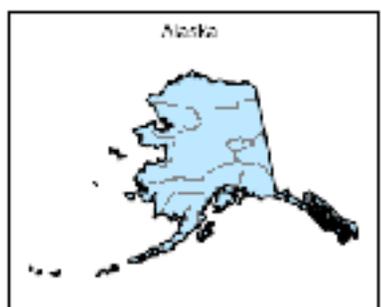

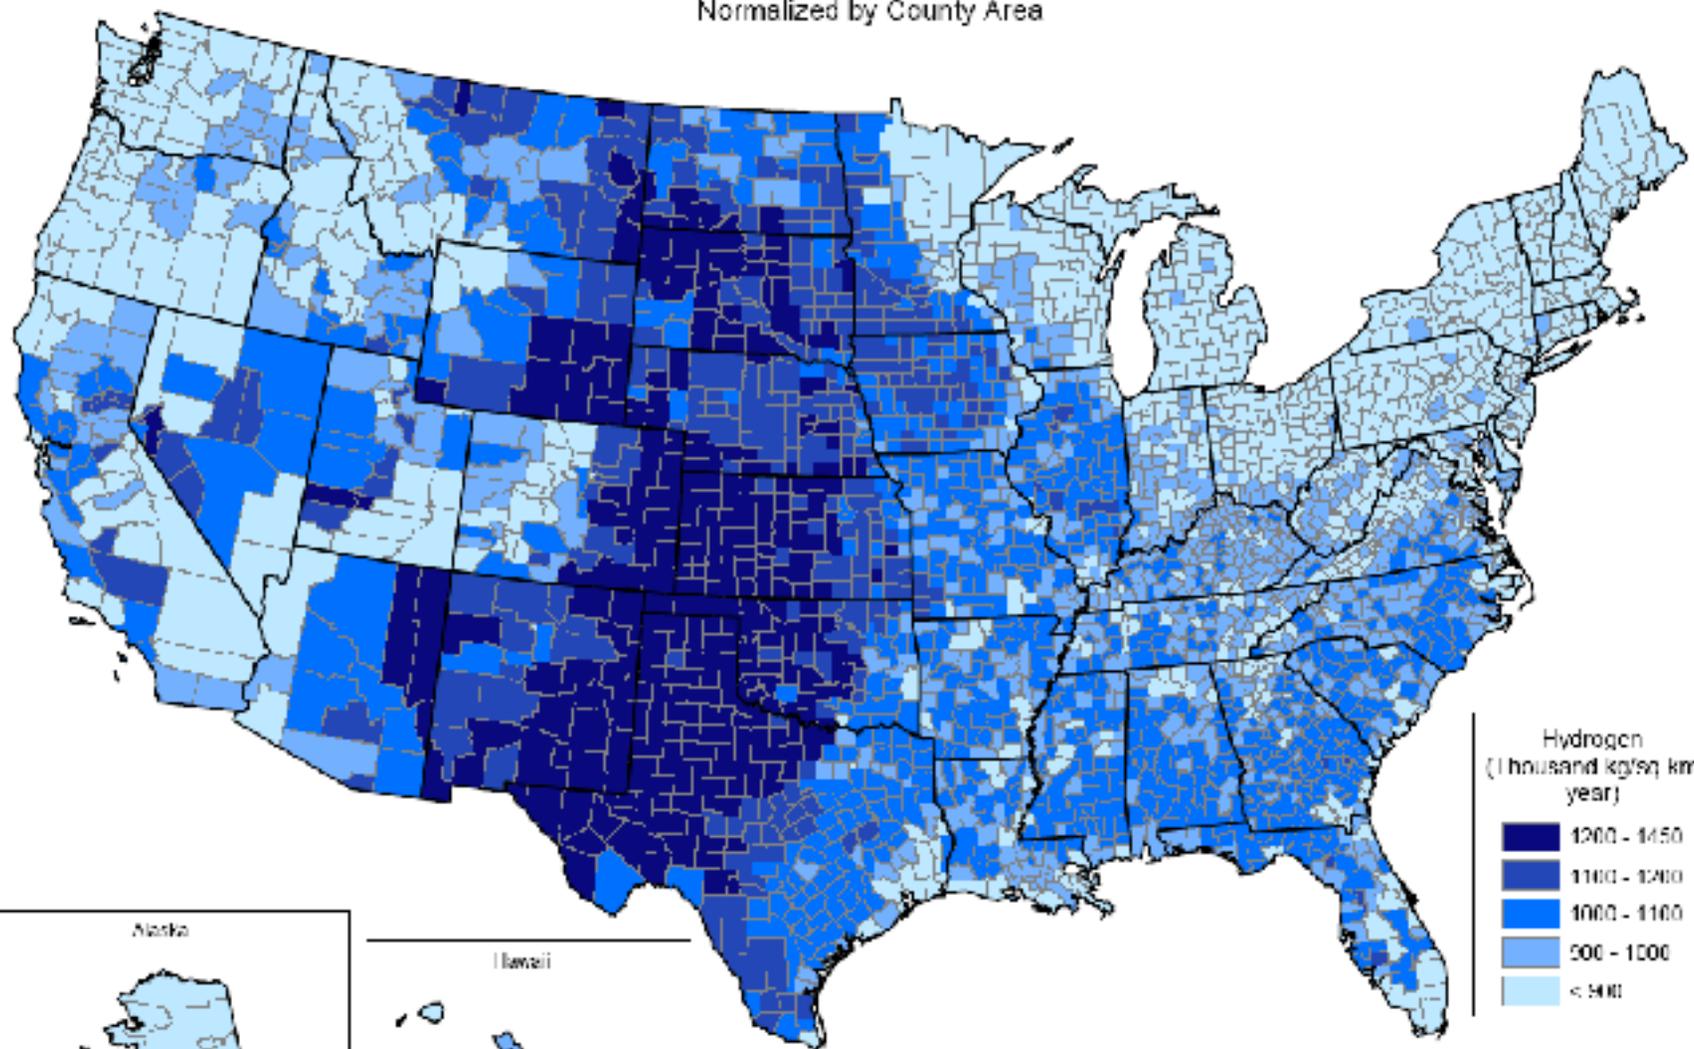

This new design will eliminate the need for a constant voltage DC bus and associated battery bank present in all systems previously studied.

Typically power electronics can be up to 30% of each system's cost.

Hydrogen Potential From Renewable Resources

Total kg of Hydrogen per County
Normalized by County Area

This analysis shows the hydrogen potential from combined renewable resources - wind and solar. No fuel conversion or additional cost associated with equipment. See additional data and analysis for more information.

Opportunities

- Wind could play a substantial role in hydrogen production at competitive prices, while reducing carbon from the generation mix
- Wind is essentially a fuel-free hydrogen generation source
 - Removes most uncertainty related to energy cost projection
 - Directly tied to capital cost of components

What might be practical?

- Levelize wind generation profile
 - Reduce risk
 - Downsize transmission
- Hydrogen fuel production at the wind site near hydrogen demand
- Electrolyzers at fueling stations creating new, controllable demand
 - Levelize load
 - Intelligent grid control
- Electrolyzers at fueling station create constant load
 - Long-term purchase agreements
